1 Executive Summary

Customers are not charged for products that they did not purchase, if the credit card companies are able to recognize fraudulent payment transactions. Data set contains transactions made by credit cards. Due to imbalancing nature of the data, many observations could be predicted as False Negative, in this case legal transactions instead of fraudulent transactions.

For example, a model that predict always 0 (Legal) can achieve an accuracy of 99.8. For that reason, the metric used for measuring the score is the Area Under The Precision-Recall Curve (AUCPR) instead of the traditional AUC curve. Expected result is an AUCPR at least greater than 0.85.

For classifying fraud detection, there are several trained algorithms such as Naive Bayes Classifier, KNN, SVM, Random Forest, GBM, XGBoost and LightGBM. To meet the goal in this analysis, using a XGBoost Model , which is capable of an AUCPR of **0.8623** .

2 Data Analysis

2.1 The Dataset

This data set presents transactions that occurred in two days, where we have **492 frauds** out of **284,807 transactions**. It is highly unbalanced, the positive class (frauds) account for 0.172% of all transactions. Due to legal ramifications detail data is not published. The data set contains only numerical input variables which are the result of a PCA transformation. Features V1, V2, ... V28 are the principal components obtained with PCA, the only features which have not been transformed with PCA are 'Time' and 'Amount'.

Dimensions

Imbalanced Dataset

This is imbalanced data set. It means that there are few rows that represent a class. In this case, only 492 transactions are frauds, represented by 1 and 284315 are not, represented by 0.

Class	Count
0	284315

Frauds over Time Distribution

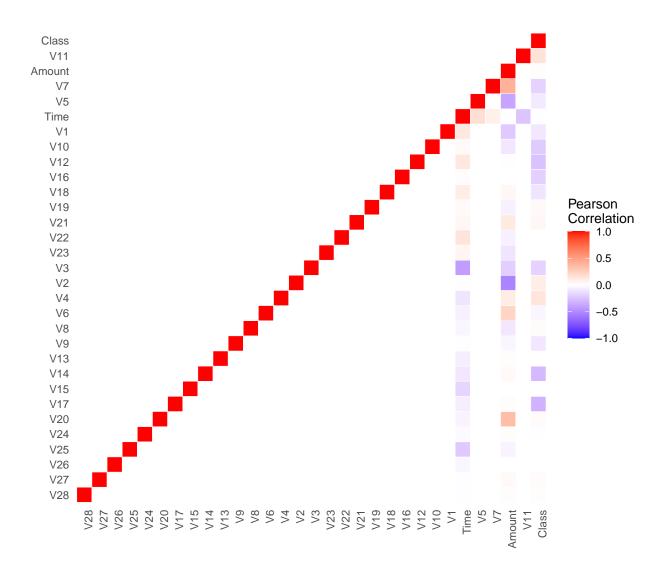

There is no correlation between time and frauds. A fraud can happen anytime. It seems not particularly useful for the modelling phase. The correlation matrix below, confirms this assumption.

Correlations between each variables

3 Data Pre-Processing and Feature Engineering

Before continuing to build models, doing data pre-processing:

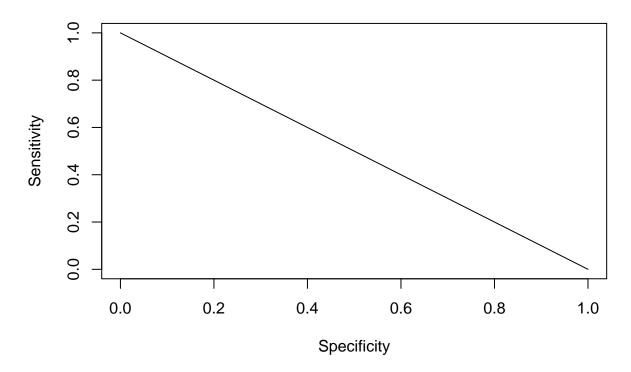

- 1. Remove the "Time" column from the data set. It isn't useful.
- 2. Split the data set into train, test, cv data set.

4 Explore Machine Learning Models

4.1 Naive Baseline Algorithm

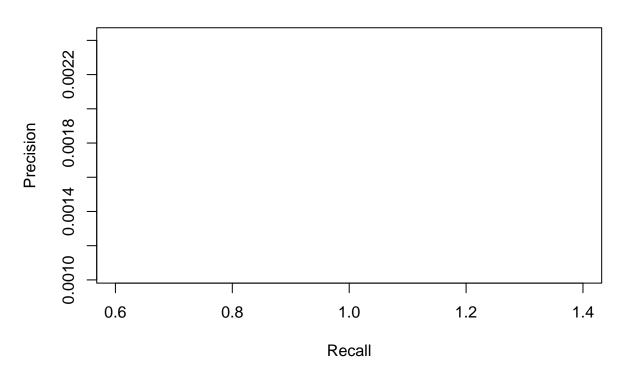

Predicting always "Legal" transaction can achieve an impressive accuracy of 99.8 and an AUC of 0.92. Because the recall and precision are 0, it is impossible to compute the AUCPR, so that is 0.

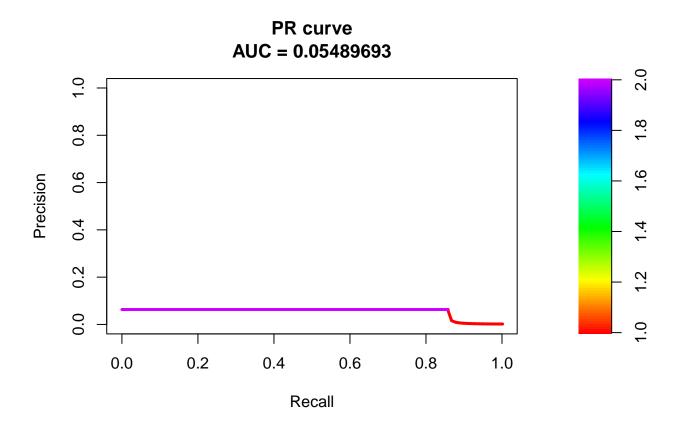

Model	AUC	AUCPR
Naive Baseline - Predicts Legal	0.5	0

AUCPR: 0

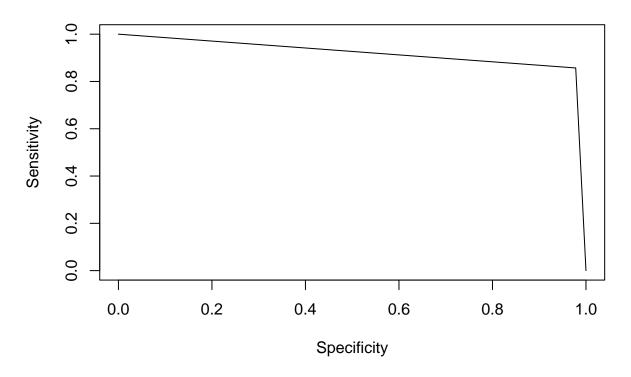

4.2 Naive Bayes

A step forward is building a Naive Bayes Classifier. The performance improve a little bit: AUC is $\bf 0.92$ and finally the there is an AUCPR of $\bf 0.05$. output is not expected way, according to the expected metric and it is easy to improve.

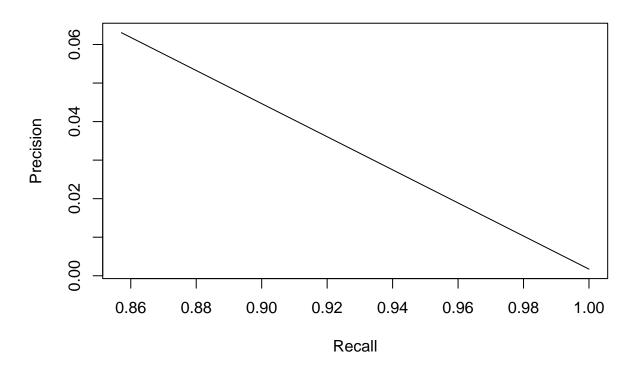

AUC: 0.917597684660626

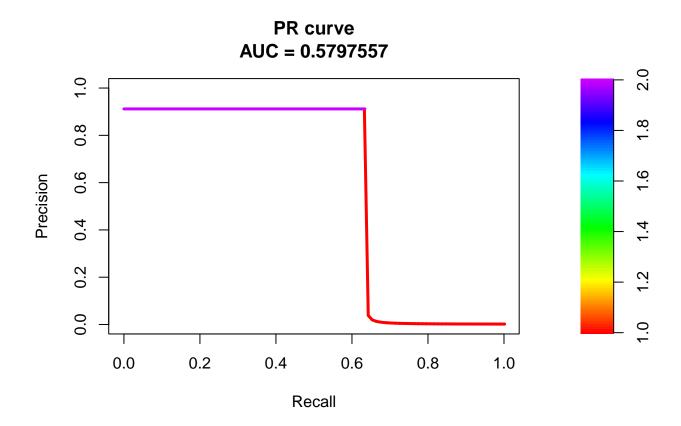

Model	AUC	AUCPR
Naive Baseline - Predicts Legal	0.5000000	0.0000000
Naive Bayes	0.9175977	0.0548969

AUCPR: 0.0548969303984264

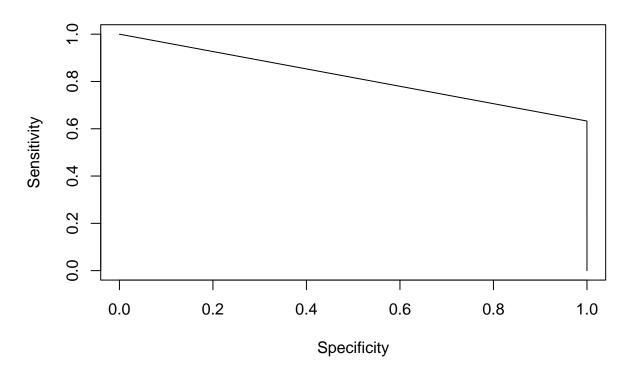

4.3 KNN - K-Nearest Neighbors

A KNN Model with k=5 can achieve a significant improvement with respect to the previous models, as regard AUCPR of 0.58 at the expense of a little drop off AUC, that is 0.81.

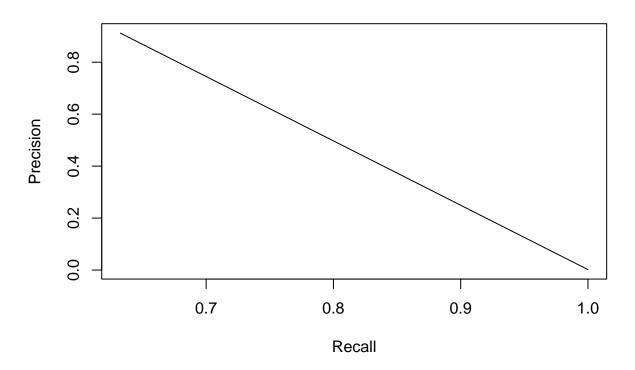

AUC: 0.816273772228058

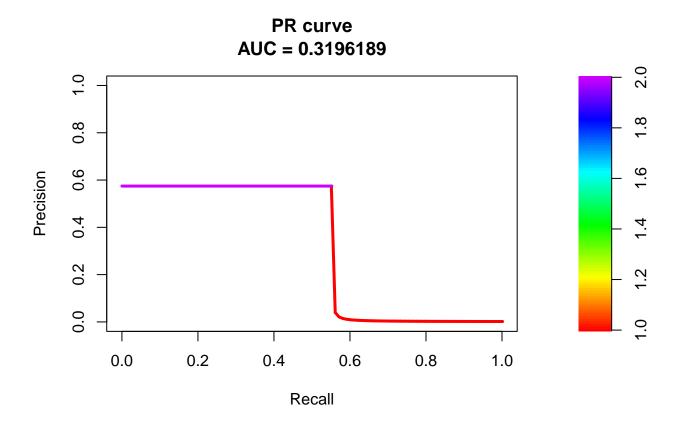

Model	AUC	AUCPR
Naive Baseline - Predicts Legal	0.5000000	0.0000000
Naive Bayes	0.9175977	0.0548969
K-Nearest Neighbors k=5	0.8162738	0.5797557

AUCPR: 0.579755719213291

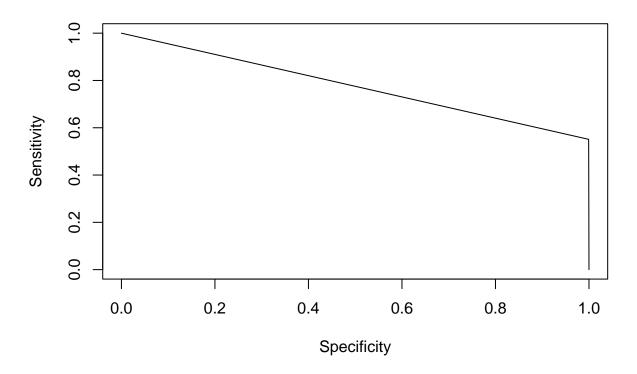

4.4 SVM - Support Vector Machine

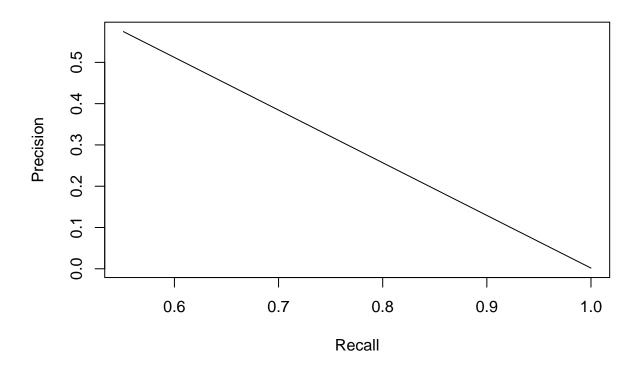

The SVM Model with a Sigmoid Kernel represent a step back on all fronts because the AUCPR is $\bf 0.32$ and AUC is $\bf 0.77$.

AUC: 0.775158481520389

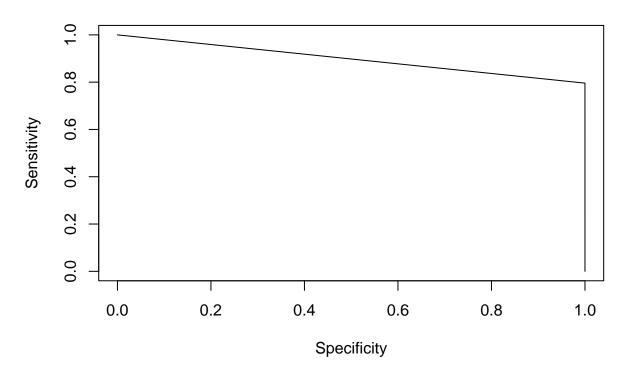

Model	AUC	AUCPR
Naive Baseline - Predicts Legal	0.5000000	0.0000000
Naive Bayes	0.9175977	0.0548969
K-Nearest Neighbors k=5	0.8162738	0.5797557
SVM - Support Vector Machine	0.7751585	0.3196189

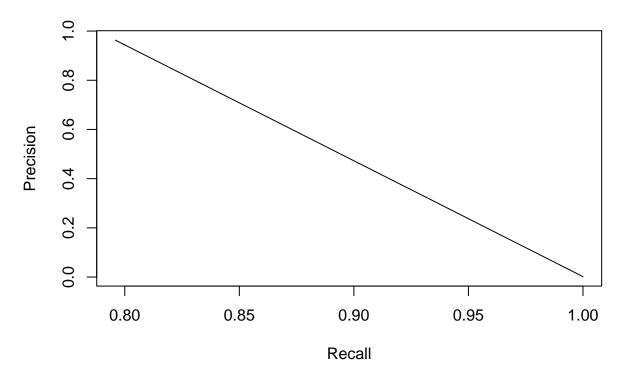

4.5 Random Forest

The ensemble methods are capable of a significant increase in performance. At the expense of another little drop off in terms of AUC (0.9) respect to the Naive Bayes model, there is a huge step forward in terms of AUCPR, that is 0.77. This model doesn't reach the desired performance (AUCPR > 0.85), but it's close to it. As the plot and the table below suggest, there are few predictors like V17, V12 and V14 that are particularly useful for classifying a fraud.

AUC: 0.897932804481376

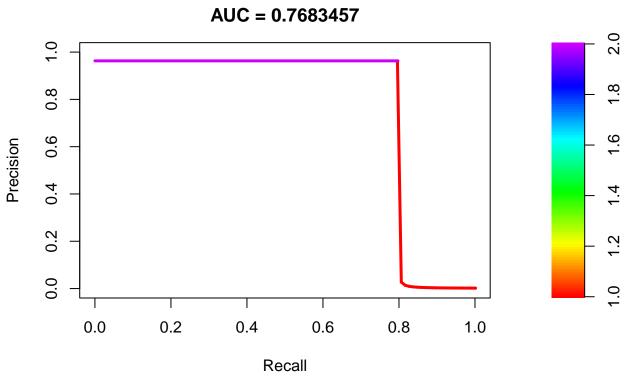

AUCPR: 0.768345660673728

Model	AUC	AUCPR
Naive Baseline - Predicts Legal	0.5000000	0.0000000
Naive Bayes	0.9175977	0.0548969
K-Nearest Neighbors k=5	0.8162738	0.5797557
SVM - Support Vector Machine	0.7751585	0.3196189

4.6 GBM - Generalized Boosted Regression

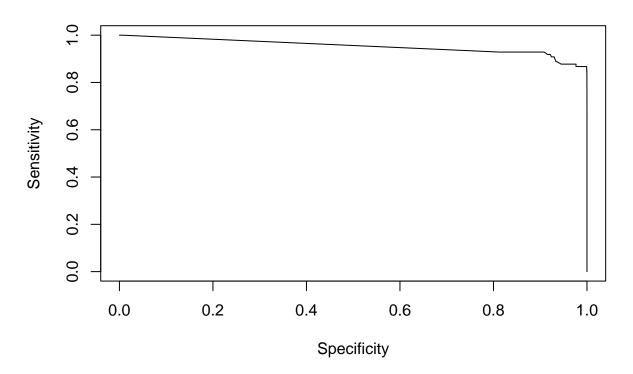

The GBM performance is really good: with an AUC of $\bf 0.95$ and AUCPR of $\bf 0.94$, It doesn't achieve the target for a breath. As the Random Forest model shows, the $\bf V17$ and $\bf V14$ are still relevant to predict a fraud.

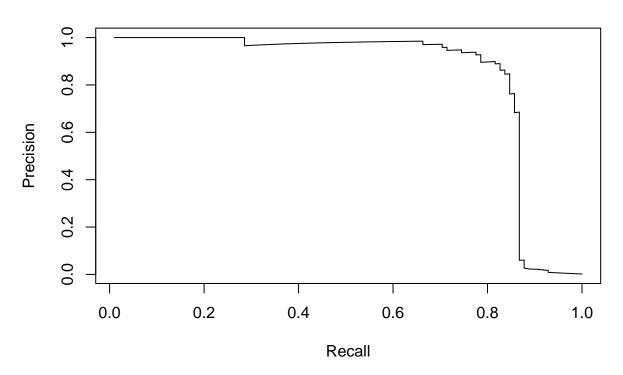

AUC: 0.953857319795125

Model	AUC	AUCPR

4.7 XGBoost- eXtreme Gradien Boosting

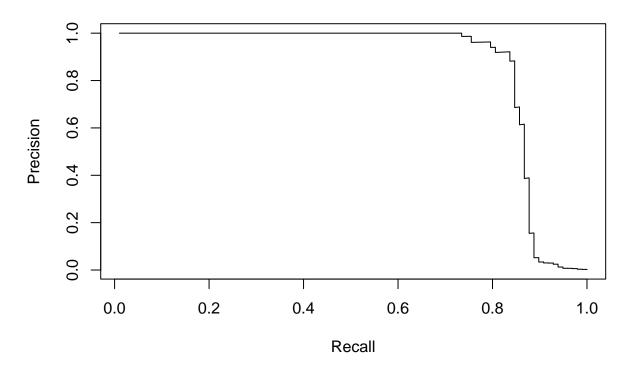

XGBoost is eXtreme Gradien Boosting package . This technique has been shown to produce models with high predictive accuracy. With an AUC of $\bf 0.98$ and an AUCPR of $\bf 0.86$ it has met expected metrics . As the previous model shown, $\bf V17$ and $\bf V14$ are still relevant to predict a fraud.

```

4.8 LightGBM: Light Gradient Boosting Machine

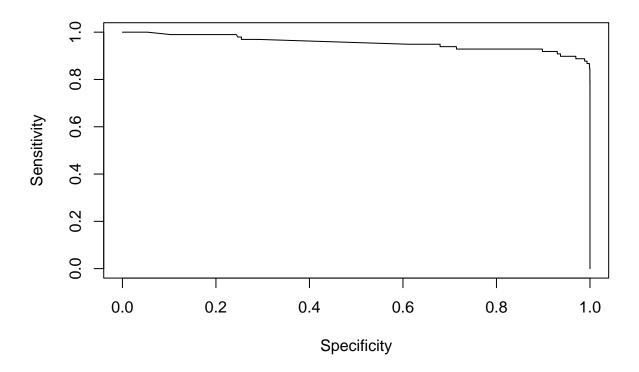

LightGBM is the efficient and complex implementation of GBM. It has lot of parameters and because of this it has a steep learning curve. With a small change of the parameters, the LightGBM model is able to reach the performance of XGBoost, performance is bit worse: AUC of **0.95** and AUCPR of **0.85**.

5 Results

Summary of all the models built for trained and validated.

6 Conclusion

The ensemble methods once again confirm themselves as among the best models out there. It easy to find them as a winners of numerous Kaggle's competitions or on TOP5 of them. Here, XGBoost model can achieve a very good AUCPR result of **0.86** and the others ensemble methods are very close to it. As the features importance plots and table show, there are few predictors like **V17** and **V14** that are particularly useful for classifying a fraud. The SMOTE technique (a technique for dealing with imbalanced data) could improve the performance a bit.
